

A. An Bian, Joachim M. Buhmann, Andreas Krause and Sebastian Tschiatschek

Problem Setting & Applications

Ground set $\mathcal{V} = \{1, \dots, n\}$: all “experiments” in experimental design, all variables in continuous programs, all R.V.s in sparse approx. ...

Utility function $F(S)$: $2^{\mathcal{V}} \mapsto \mathbb{R}_+$, monotone ($A \subseteq B \Rightarrow F(A) \leq F(B)$)
But non-submodular/non-supermodular! 😞

Task $\max_{S \subseteq \mathcal{V}, |S| \leq k} F(S)$: select a subset of items with budget k , to maximize the utility $F(S)$

Class I [combinatorial objectives]: Bayesian experimental design [Chaloner '95, Krause '08], Sparse Gaussian processes [Lawrence '03], Column subset selection [Altschuler '16] ...

Class II [auxiliary set fn. in continuous opt. with sparsity constraints $\max_{|\text{supp}(x)| \leq k} f(x)$] $F(S) := \max_{\text{supp}(x) \subseteq S} f(x) \rightarrow \max F(S)$: Feature selection [Guyon '03], Sparse approx. [Das '08, Krause '10, Elenberg '16], Sparse recovery [Candes '03], Sparse M-estimation [Jain '14], LP with combinatorial constraints ...

Empirically, GREEDY is used for non-submodular objectives.

The GREEDY Algorithm

```

 $S^0 \leftarrow \emptyset$ 
For  $t = 1, \dots, k$  do
     $v^* \leftarrow \text{argmax}_{v \in \mathcal{V} \setminus S^{t-1}} p_v(S^{t-1})$ 
     $S^t \leftarrow S^{t-1} \cup \{v^*\}$ 
Output  $S^k$  (GREEDY output)
  
```

Marginal gain:
 $p_v(S) := F(S \cup \{v\}) - F(S)$

How Good is GREEDY?

Right fig: Bayesian A-optimality $F_A(S)$: reduction of variance in the posterior of parameters.

😊 non-submodular/non-supermodular

👉 Why GREEDY is So Good?

👉 First tight guarantee for GREEDY on k -cardinality non-submodular maximization, combining two parameters (α, γ)

👉 Bounding (α, γ) for non-trivial applications

Approximation Guarantee

$$\text{GREEDY output}$$

$$F(S^k) \geq \alpha^{-1} \left[1 - \left(\frac{k-\alpha\gamma}{k} \right)^k \right] F(\Omega^*) \geq \alpha^{-1} (1 - e^{-\alpha\gamma}) F(\Omega^*)$$

$\alpha \in [0,1]$ $\gamma \in [0,1]$

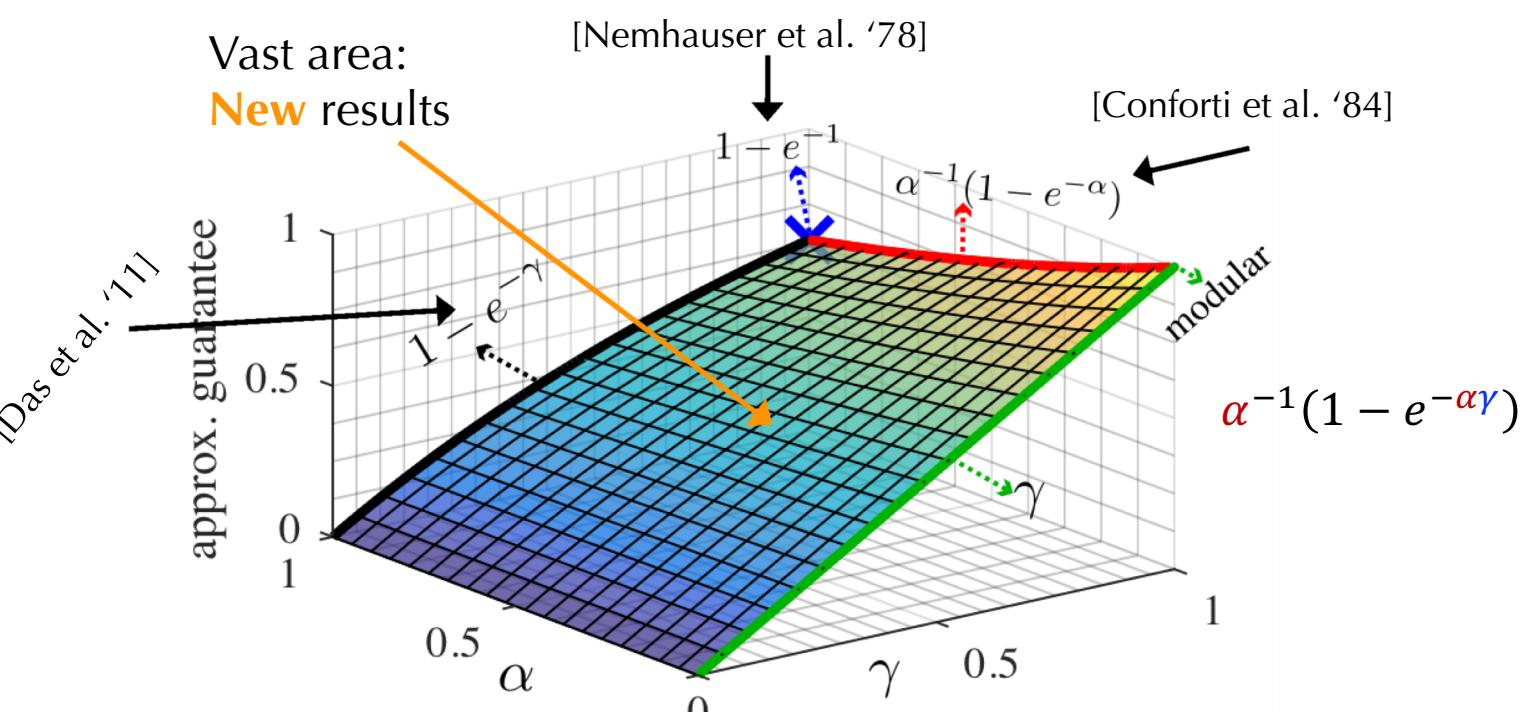

Generalized curvature: smallest scalar α s.t. $\forall \Omega, S \subseteq \mathcal{V}, i \in S \setminus \Omega, \rho_i(S \setminus \{i\} \cup \Omega) \geq (1 - \alpha)\rho_i(S \setminus \{i\})$

😊 F is supermodular iff $\alpha = 0$
 α How close F is from being supermodular

Submodularity ratio: [Das et al. '11]
largest scalar γ s.t. $\forall \Omega, S \subseteq \mathcal{V} \setminus \Omega, \sum_{\omega \in \Omega \setminus S} \rho_\omega(S) \geq \gamma \rho_\Omega(S)$

😊 F is submodular iff $\gamma = 1$
 γ To what extent F has submodular property

α and γ can be bounded for non-trivial applications 😊

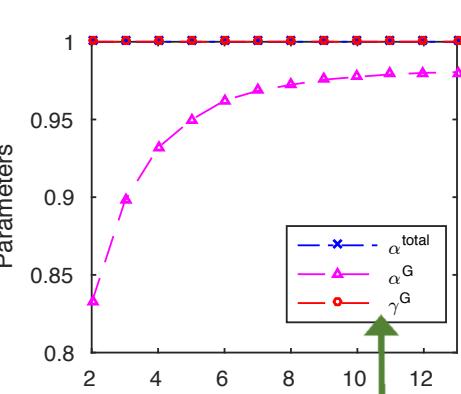

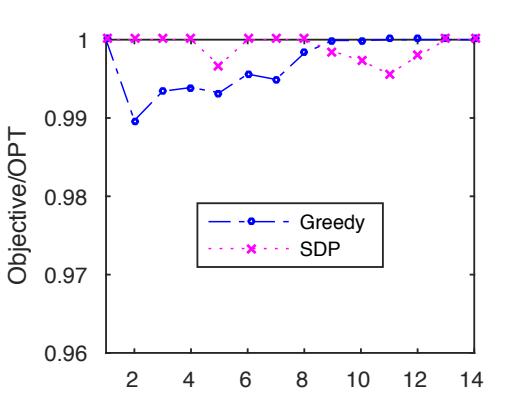

Corollary: If F is supermodular ($\alpha = 0$, green line above), then approx. guarantee is γ . ($\lim_{\alpha \rightarrow 0} \alpha^{-1}(1 - e^{-\alpha\gamma}) = \gamma$)

Experiments: Bayesian A-optimality

$\alpha^{\text{total}} := 1 - \min_{i \in \mathcal{V}} \rho_i(\mathcal{V} \setminus \{i\}) / \rho_i(\emptyset)$, classical curvature for submodular fn.
😊 less expressive than generalized curvature α

Real-World Results

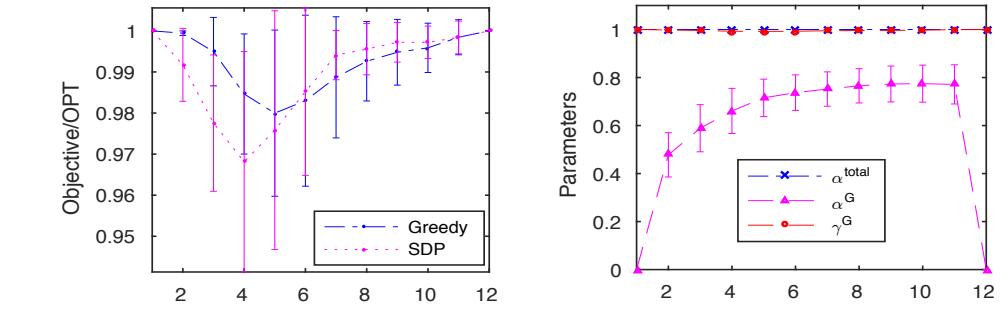

Boston Housing data, $n = 14$ samples, 14 features
SDP: classical algorithm, but poor scalability

α^G, γ^G : Greedy/refined version of α, γ . In definitions, restrict $S \rightarrow$ GREEDY trajectory, $|\Omega| = k$

Synthetic Results

$n = 12$ samples, 6 features, random observations from a multivariate Gaussian with different correlations (0.2 in figs below, 20 repetitions)

	d: 60 n: 80	d: 40 n: 112	d: 64 n: 128	d: 100 n: 200	d: 120 n: 250
GREEDY	0.278	0.360	0.765	4.666	10.56
SDP	95.2	115.2	205.4	1741.2	3883.5
SDP/GREEDY	341.7	319.9	268.7	373.2	367.7

Greedy is 2 orders of magnitude faster than SDP!

Timing

Approximation Guarantee

$$F(S^k) \geq \alpha^{-1} \left[1 - \left(\frac{k-\alpha\gamma}{k} \right)^k \right] F(\Omega^*) \geq \alpha^{-1} (1 - e^{-\alpha\gamma}) F(\Omega^*)$$

$\alpha \in [0,1]$ $\gamma \in [0,1]$

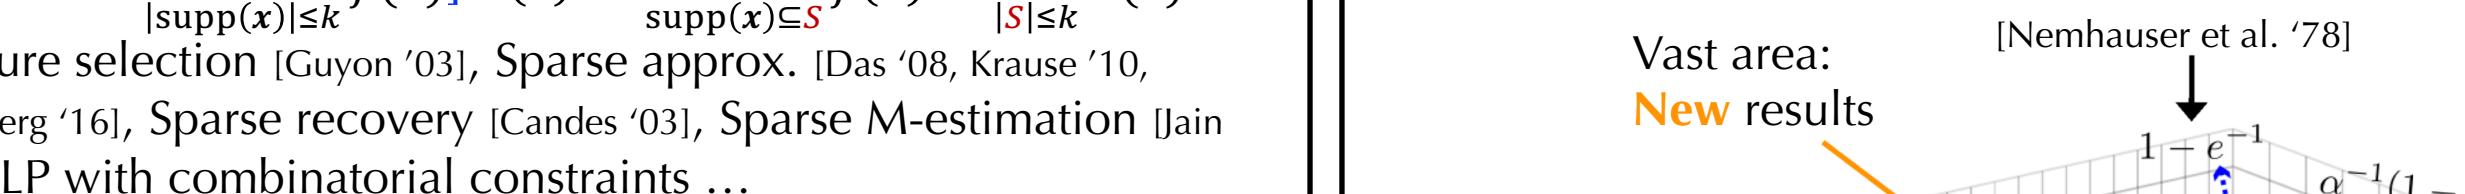

Generalized curvature: smallest scalar α s.t. $\forall \Omega, S \subseteq \mathcal{V}, i \in S \setminus \Omega, \rho_i(S \setminus \{i\} \cup \Omega) \geq (1 - \alpha)\rho_i(S \setminus \{i\})$

😊 F is supermodular iff $\alpha = 0$
 α How close F is from being supermodular

Submodularity ratio: [Das et al. '11]
largest scalar γ s.t. $\forall \Omega, S \subseteq \mathcal{V} \setminus \Omega, \sum_{\omega \in \Omega \setminus S} \rho_\omega(S) \geq \gamma \rho_\Omega(S)$

😊 F is submodular iff $\gamma = 1$
 γ To what extent F has submodular property

α and γ can be bounded for non-trivial applications 😊

Corollary: If F is supermodular ($\alpha = 0$, green line above), then approx. guarantee is γ . ($\lim_{\alpha \rightarrow 0} \alpha^{-1}(1 - e^{-\alpha\gamma}) = \gamma$)

Tightness Result

$\forall \alpha \in [0, 1], \gamma \in (0, 1], \exists$ set functions achieving the guarantee exactly

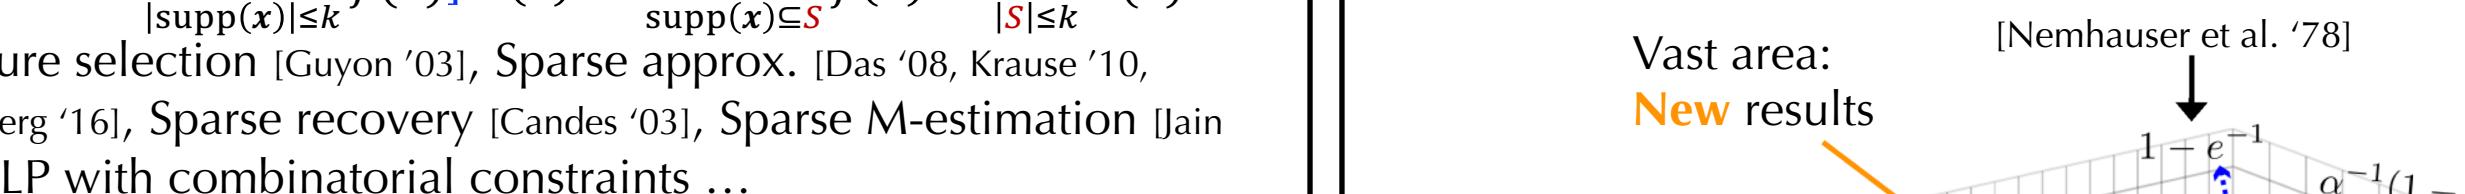

Construction: \mathcal{V} contains elements in $S := \{j_1, \dots, j_k\}$, $\Omega := \{\omega_1, \dots, \omega_k\}$ ($S \cap \Omega = \emptyset$), & $n = 2k$ "dummy" elements

$F(T) := \frac{f(|\Omega \cap T|)}{k} (1 - \alpha\gamma \sum_{i:j_i \in S \cap T} \xi_i) + \sum_{i:j_i \in S \cap T} \xi_i$, where $\xi_i := \frac{1}{k} \left(\frac{k-\alpha\gamma}{k} \right)^{i-1}$, $i = 1, \dots, k$, $f(x) := \frac{\gamma^{-1}-1}{k-1} x^2 + \frac{k-\gamma^{-1}}{k-1}$

$F(T)$: monotone, has curvature α and submodularity ratio γ

GREEDY outputs S (proof by induction), optimal solution: Ω

$F(S) = \alpha^{-1} [1 - \left(\frac{k-\alpha\gamma}{k} \right)^k] \rightarrow$ matching the bound

Corollary: If F is supermodular ($\alpha = 0$, green line above), then approx. guarantee is γ . ($\lim_{\alpha \rightarrow 0} \alpha^{-1}(1 - e^{-\alpha\gamma}) = \gamma$)

Bounding α & γ for Applications

👉 Bayesian A-optimality: $y = X^\top \theta + \epsilon, \epsilon \sim \mathcal{N}(0, \sigma^2 I), \theta \sim \mathcal{N}(0, \beta^{-2} I)$. $F_A(S) = \text{const} - \text{tr}((\beta^2 I + \sigma^{-2} X_S X_S^\top)^{-1})$.

Assume normalized data $\|x_i\| = 1, \forall i \in \mathcal{V}, \|X\| < \infty$.

$$\gamma \geq \frac{\beta^2}{\|X\|^2(\beta^2 + \sigma^{-2}\|X\|^2)} \quad \alpha \leq 1 - \frac{\beta^2}{\|X\|^2(\beta^2 + \sigma^{-2}\|X\|^2)}$$

👉 Determinantal function of a square submatrix: sparse Gaussian process $F(S) = \det(I + \Sigma_S), \Sigma$: covariance matrix. $F(S)$ is supermodular ($\alpha =$
